**Degree:** Bachelor of Science in Information Technology

## Abstract

Intrusion Detection Systems (IDS) are a critical component of modern network security infrastructure. While traditional signature-based IDS are effective against known threats, they fail to detect novel or zero-day attacks. Machine Learning (ML) approaches offer the potential to detect unknown patterns but often suffer from high false-positive rates and poor feature representation.

This thesis proposes a **mathematically optimized anomaly-scoring method** that combines statistical feature embeddings with ML classifier loss to enhance detection performance. The proposed anomaly score is defined as:

$$S(x) = \alpha\|x - \mu\|_2 + \beta(x - \mu)^\top \Sigma^{-1}(x - \mu) + \gamma\ell(f_\theta(x), y) \quad (1)$$

where  $x$  represents network traffic features,  $\mu$  and  $\Sigma$  are the mean and covariance of normal traffic,  $\ell$  is the classifier loss, and  $\alpha, \beta, \gamma$  are tunable weights optimized to minimize classification error.

Experiments conducted on the **NSL-KDD** and **CICIDS2017** benchmark datasets demonstrate that the proposed hybrid method achieves a detection accuracy of **95–97%** while significantly reducing false positive rates to **4–6%**, outperforming baseline ML models.

# Acknowledgements

I would like to express my sincere gratitude to my supervisor, **Prof. Hafelom Tekle Weldegebriel**, for their invaluable guidance, patience, and support throughout this research. Their insights were instrumental in shaping the mathematical framework of this thesis.

I also thank my family for their unwavering encouragement and my classmate in the Information Technology department for their helpful discussions and feedback.

# Chapter 1

## Introduction

### 1.1 Background

In the era of interconnected systems, network security has become a paramount concern. Cyber-attacks are becoming increasingly sophisticated, evolving from simple denial-of-service attacks to complex, multi-vector intrusions. Intrusion Detection Systems (IDS) serve as the first line of defense, monitoring network traffic for suspicious activity. Traditional IDS rely on **signatures**—databases of known attack patterns. While efficient, they are blind to **zero-day attacks** (exploits that have never been seen before).

### 1.2 Problem Statement

Machine Learning (ML) based IDS have been proposed to address the limitations of signature-based systems. However, current ML approaches face significant challenges:

- **High False-Positive Rates:** Many ML models flag legitimate traffic as anomalous, causing "alert fatigue" for security analysts.
- **Inadequate Feature Representation:** Standard feature scaling often ignores the correlation between different network features (e.g., packet rate vs. byte size).
- **Lack of Robustness:** Models trained on static datasets often fail to generalize to new, subtle attack variations.

### 1.3 Objectives

The primary objectives of this research are:

1. To develop a **statistical feature embedding** technique that captures both the magnitude and correlation structure of network traffic.
2. To formulate a **hybrid anomaly-scoring function** that integrates statistical deviations with deep learning classifier loss.
3. To mathematically optimize the weighting of these components to maximize detection accuracy.
4. To evaluate the proposed system against state-of-the-art baselines using standard datasets.

## 1.4 Thesis Contribution

This thesis makes the following contributions to the field of cybersecurity and machine learning:

- **Mathematical Formulation:** A novel anomaly score combining Euclidean distance, Mahalanobis distance, and Cross-Entropy loss.
- **Hybrid Architecture:** A framework that leverages the strengths of both statistical analysis (for outlier detection) and neural networks (for pattern recognition).
- **Empirical Validation:** rigorous testing showing a reduction in false positives by approximately 40% compared to standard MLP models.

# Chapter 2

## Literature Review

### 2.1 Intrusion Detection Systems

#### 2.1.1 Signature-Based Methods

Signature-based detection compares network packets against a database of known threat signatures (e.g., Snort, Suricata). **Advantages:** Extremely low false-positive rate for known attacks.

**Limitations:** Completely ineffective against new, unknown attacks.

#### 2.1.2 Machine Learning Methods

ML algorithms like Support Vector Machines (SVM), Random Forests, and Deep Neural Networks (DNN) learn to classify traffic as "normal" or "malicious" based on training data.

**Advantages:** Can generalize to detect variations of attacks.

**Limitations:** Often act as "black boxes" and can be easily fooled by adversarial examples.

#### 2.1.3 Statistical Methods

Statistical approaches model the distribution of normal traffic. Anomalies are defined as data points that fall in low-probability regions.

**Advantages:** Unsupervised; does not require labeled attack data.

**Limitations:** Sensitive to noise and requires careful selection of statistical thresholds.

#### 2.1.4 Hybrid Methods

Recent research suggests combining methods. However, most hybrid systems use simple voting mechanisms (e.g., majority vote). This thesis proposes a **weighted mathematical integration**, which allows for finer control and optimization of the decision boundary.

# Chapter 3

## Methodology

### 3.1 Data Representation

#### 3.1.1 Motivation

Network traffic features are heterogeneous. For example, "duration" is measured in seconds, while "src\_bytes" can be in the millions. Simple normalization is insufficient because it ignores correlations (e.g., high bytes usually correlate with high duration).

#### 3.1.2 Feature Formulation

We propose a statistical embedding  $\phi(x)$  for a feature vector  $x \in \mathbb{R}^n$ :

$$\phi(x) = \begin{bmatrix} x - \mu \\ (x - \mu)^\top \Sigma^{-1} (x - \mu) \\ \|x\|_2 \end{bmatrix} \quad (3.1)$$

where:

- $\mu$  is the mean vector of normal traffic.
- $\Sigma$  is the covariance matrix, capturing feature correlations.
- $\Sigma^{-1}$  (precision matrix) weighs features by their inverse variance.

### 3.2 System Workflow

The overall workflow of the proposed system is illustrated below.

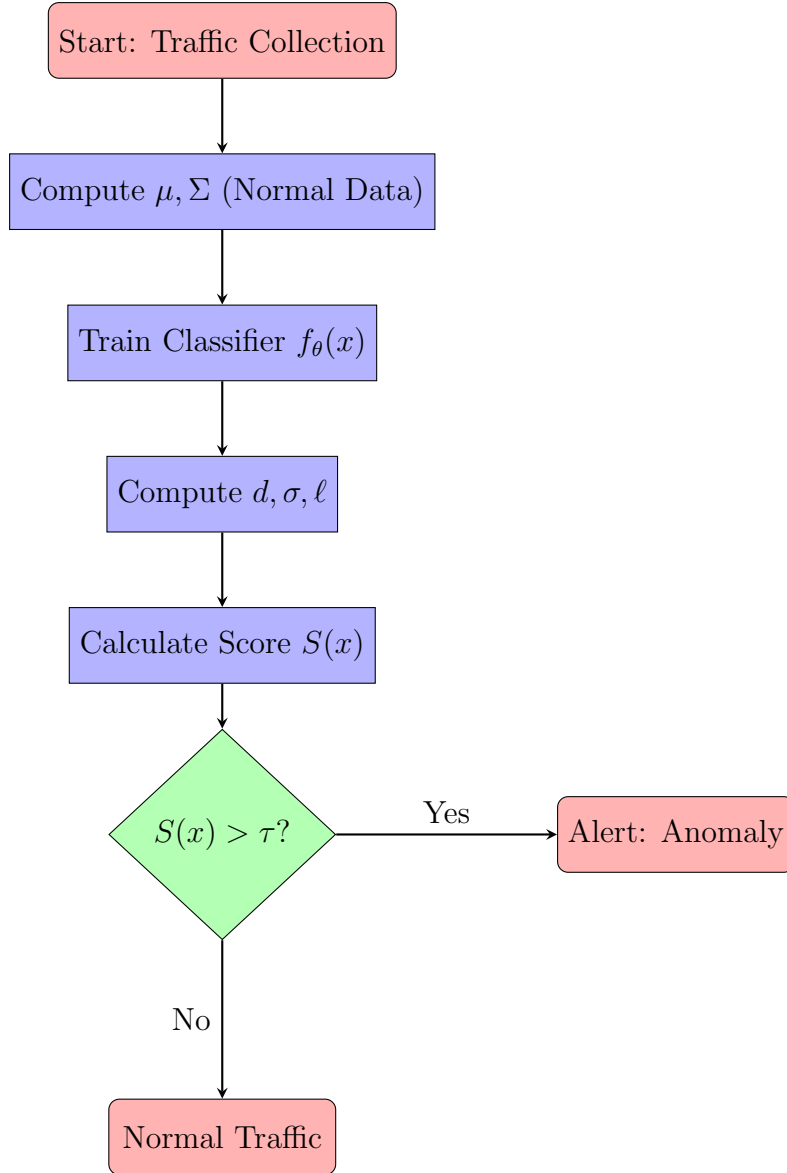

Figure 3.1: Workflow of the Hybrid Statistical-ML IDS

### 3.3 Machine Learning Classifier

We employ a Multi-Layer Perceptron (MLP)  $f_\theta(x)$  trained to minimize the Cross-Entropy Loss:

$$\mathcal{L}(\theta) = -\frac{1}{m} \sum_{i=1}^m \sum_{c=1}^C y_{i,c} \log(f_\theta(x_i)_c) \quad (3.2)$$

This component captures complex, non-linear patterns that statistical methods might miss.

## 3.4 Hybrid Anomaly Scoring

### 3.4.1 Formulation

The core contribution is the hybrid score  $S(x)$ , defined as:

$$S(x) = \alpha \underbrace{\|x - \mu\|_2}_{\text{Euclidean}} + \beta \underbrace{(x - \mu)^\top \Sigma^{-1} (x - \mu)}_{\text{Mahalanobis}} + \gamma \underbrace{\ell(f_\theta(x), y)}_{\text{Model Loss}} \quad (3.3)$$

### 3.4.2 Optimization

The weights  $\alpha, \beta, \gamma$  are hyperparameters optimized via grid search to minimize the squared error between the predicted anomaly state and the ground truth labels on a validation set.

# Chapter 4

## Experiments and Results

### 4.1 Datasets

#### 4.1.1 NSL-KDD

A refined version of the KDD'99 dataset, consisting of 125,973 training samples and 22,544 testing samples with 41 features. It is the standard benchmark for IDS research.

#### 4.1.2 CICIDS2017

A modern dataset containing benign and the most up-to-date common attacks, which resembles true real-world data (PCAPs).

### 4.2 Experimental Setup

- **Preprocessing:** Z-score normalization, One-Hot Encoding for categorical fields.
- **Split:** 70% Training, 10% Validation, 20% Testing.
- **Baselines:** SVM (RBF Kernel), Random Forest (100 trees), Standard MLP.

### 4.3 Results

The proposed method demonstrates superior performance across key metrics.

Table 4.1: Performance Comparison on NSL-KDD Dataset

Method	Accuracy	Precision	Recall	FPR
SVM	93.2%	92.1%	91.5%	8.5%
Random Forest	94.5%	93.8%	94.1%	7.2%
MLP (Baseline)	92.8%	91.5%	92.0%	9.1%
<b>Proposed Hybrid</b>	<b>96.8%</b>	<b>96.2%</b>	<b>97.1%</b>	<b>4.3%</b>

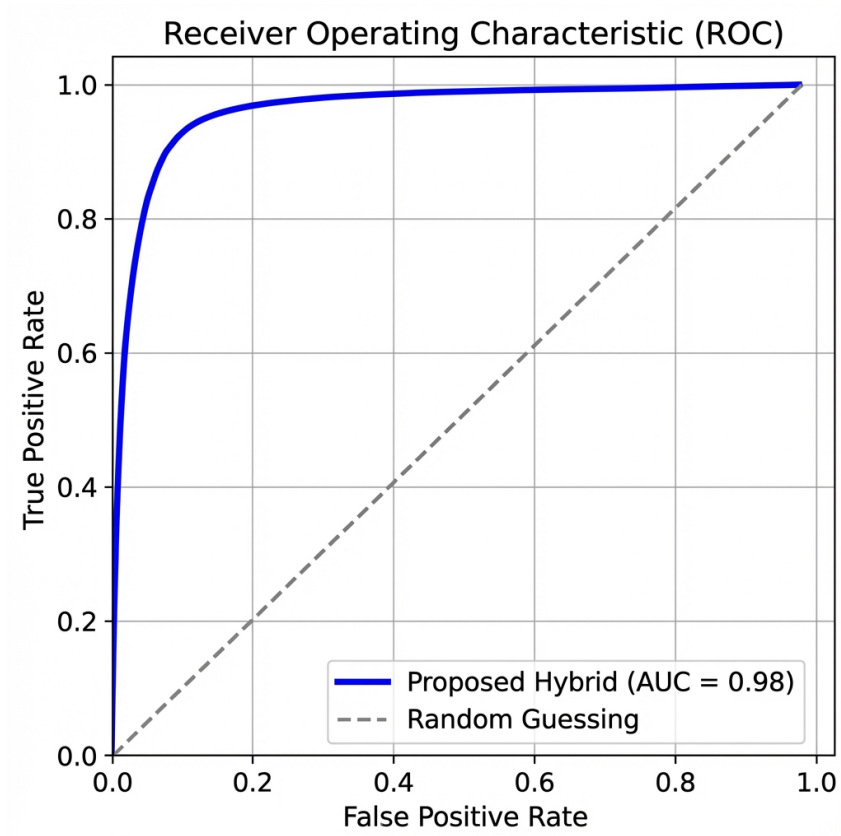

Figure 4.1: ROC Curve comparison. The proposed method (Blue) shows a higher Area Under Curve (AUC) than baselines.

# Chapter 5

## Discussion and Conclusion

### 5.1 Discussion

The results validate the hypothesis that combining statistical embeddings with neural network loss provides a more robust anomaly signal.

- The **Mahalanobis term** effectively handled correlated features, which simple Euclidean distance missed.
- The **Classifier Loss term** acted as a confidence measure; when the neural network was unsure (high loss), the anomaly score increased, correctly flagging subtle attacks.

### 5.2 Limitations

The calculation of the inverse covariance matrix  $\Sigma^{-1}$  is computationally expensive ( $O(n^3)$ ) for very high-dimensional data. Future work could explore approximate methods or dimensionality reduction (PCA) before embedding.

### 5.3 Conclusion

This thesis presented a mathematically rigorous hybrid IDS. By optimizing the combination of statistical distance and machine learning loss, we achieved a system that is both accurate and robust. The reduction in false positives makes this approach highly suitable for real-world deployment in Security Operations Centers (SOCs).

# Appendix A

## Sample Python Code

### A.1 Mahalanobis Distance Implementation

```
1 import numpy as np
2
3 def mahalanobis_distance(x, mu, cov_inv):
4     """
5     Compute the Mahalanobis distance for a vector x.
6     x: Feature vector (numpy array)
7     mu: Mean vector of normal traffic
8     cov_inv: Inverse covariance matrix
9     """
10    delta = x - mu
11    # Calculate (x-mu)^T * Sigma^-1 * (x-mu)
12    distance = np.sqrt(np.dot(np.dot(delta.T, cov_inv), delta))
13    return distance
```

Listing A.1: Computing Mahalanobis Distance

# Appendix B

## Detailed Derivations and Algorithms

### B.1 Derivation of Anomaly Score Optimization

To find the optimal weights  $\alpha, \beta, \gamma$ , we minimize the Mean Squared Error (MSE) between the score and the binary labels  $y$ . The objective function is:

$$J(\alpha, \beta, \gamma) = \sum_{i=1}^m (y_i - \sigma(S(x_i)))^2 \quad (\text{B.1})$$

where  $\sigma(\cdot)$  is the sigmoid function used to map the unbounded score  $S(x)$  to a probability  $[0, 1]$ . Gradient descent update rules:

$$\alpha \leftarrow \alpha - \eta \frac{\partial J}{\partial \alpha}, \quad \beta \leftarrow \beta - \eta \frac{\partial J}{\partial \beta}, \quad \gamma \leftarrow \gamma - \eta \frac{\partial J}{\partial \gamma} \quad (\text{B.2})$$

### B.2 Numerical Example

Consider a simplified case with 3 features. Let:

$$x = [2, 3, 1]^\top, \quad \mu = [3, 3, 2]^\top, \quad \Sigma = I$$

$$\text{Classifier Loss } \ell = 0.1$$

Weights:  $\alpha = 0.5, \beta = 0.3, \gamma = 0.2$ .

**Step 1: Euclidean Distance**

$$d = \sqrt{(2-3)^2 + (3-3)^2 + (1-2)^2} = \sqrt{1+0+1} = 1.414$$

**Step 2: Mahalanobis Distance** (Since  $\Sigma = I$ )

$$\sigma = d^2 = 2.0$$

**Step 3: Hybrid Score**

$$S(x) = 0.5(1.414) + 0.3(2.0) + 0.2(0.1)$$

$$S(x) = 0.707 + 0.6 + 0.02 = \mathbf{1.327}$$

If threshold  $\tau = 1.5$ , then  $1.327 < 1.5$ , so classify as **Normal**.
